There are two major hypotheses about the role of the subthalamic nucleus (STN) in Parkinson's disease (PD): (1) the STN is hyperactive and tonically drives the output from the basal ganglia and is thus responsible for the cardinal symptoms of PD, or (2) the STN is chronically depressed and can only fire in response to the physiological demands of the external environment. To distinguish between these hypotheses, we analyzed the firing pattern and the response to single and to electrical double pulse stimulation of STN neurons in awake-behaving rats with partial striatal or post-surgical experimental parkinsonism. A total of 822 STN neurons were recorded in 19 normal rats, and a total of 809 STN neurons were recorded in 17 experimental parkinsonian rats. The study revealed an increased firing rate and a decreased percentage of orthodromic and antidromic spike firing at antidromically identified STN neurons in parkinsonian rats in comparison with normal rats. We hypothesized that the increased firing rate and a depressed firing pattern were the result of loss of dopamine in the striatum, whereas the differential response to electrical stimulation suggests alterations in the ion channel properties of the STN neurons. The results confirmed that the STN in animal models of PD is chronically depressed but this depression is not due to loss of dopamine in the 6a5afdab4c
