Alcohol in the liver: effects on intracellular Ca²⁺ homeostasis and membrane lipid composition. Alcoholic liver disease (ALD) is characterized by infiltration of immune cells into the liver resulting in tissue injury. Alcohol is known to affect intracellular Ca²⁺ homeostasis and several ion transporters and pumps have been associated with cellular effects of ethanol. Here, we investigate the effects of ethanol on intracellular Ca²⁺ homeostasis in rat hepatocytes. We showed that ethanol induces long lasting Ca²⁺ oscillations with a peak at 60 min. This effect is prevented by blocking gap-junctions and is not reproduced in the presence of extracellular Ca²⁺. Injection of phospholipase C (PLC) which cleaves membrane phosphatidylinositol (PI) into inositol 1,4,5-trisphosphate (IP3) and diacylglycerol (DAG) results in Ca²⁺ oscillations that are completely blocked by the IP3 receptor antagonist Xestospongine C (Xes C). We show that the membrane lipid composition in isolated hepatocytes is affected by alcohol. The degree of unsaturation of ethanol-exposed hepatocytes is decreased. Ethanol does not affect arachidonate enrichment, but increases monounsaturated fatty acids, linoleate and stearate, indicating an enrichment of total polyunsaturated fatty acids with a substantial decrease in linolenate. This indicates a modification of the fatty acid pattern in membrane lipids. Q: A partition of M by totally disconnected closed subsets Let M be a T_0
